

In Silico Optimization of Biochemical Pathways Using Elementary Conversion Modes in Microbial Community Models

Bachelor Thesis of Julia Jasovski

Course of studies: Computational Engineering Science

Supervisors: Dr. Zita Soons, Katharina Ebeling

Examiners:

Prof. Alexander Mitsos, Ph.D,

Prof. Lars Küpfer, Ph.D,

Prof. Dr. Adel Mhamdi

Introduction to constraint-based metabolic modelling

- Metabolism can be understood as a network of reactions
- Reaction network are expressed in a stoichiometric matrix S with n metabolites and m reactions [1]
- The concentration change for every metabolite is given by \dot{c}_j for $j = 1, \dots, n$

$$\begin{pmatrix} \dot{c}_1 \\ \vdots \\ \dot{c}_n \end{pmatrix} = \underbrace{\begin{pmatrix} s_{1,1} & \cdots & s_{1,m} \\ \vdots & \ddots & \vdots \\ s_{n,1} & \cdots & s_{n,m} \end{pmatrix}}_S \cdot \underbrace{\begin{pmatrix} v_1 \\ \vdots \\ v_m \end{pmatrix}}_{\text{Flux vector } v} = \begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix}$$

Possible objective:
maximize $v_{Biomass}$

- Flux Balance Analysis (FBA) is currently used to optimize such constraint-based metabolic models [2]
- **Problem:** It requires prior knowledge of metabolic uptake rates and only considers optimal pathways

We are interested in all possible pathways

Motivation Elementary Conversion Mode

- Elementary Flux Mode (EFM) analysis enumerates all possible pathways in a network
- Problem:** Huge number of EFMs and often infeasible with a lot of redundancy in the conversion
- Elementary Conversion Mode (ECM) analysis identifies all overall conversions from nutrients to products ^[1]
⇒ focuses only on external metabolites
- The internal metabolites $j \in Int$ are assumed to be steady state
⇒ $\dot{c}_j = 0$ for all $j \in Int$
- The conic combination of every ECM can be described as a steady-state conversion cone:

$$C = \{\dot{c}_{ext} \in \mathbb{R}^l : \dot{c}_{ext} = Ev, v \geq 0\}, \quad l = \# \text{ of external metabolites}$$

Visualization of an ECM-Matrix

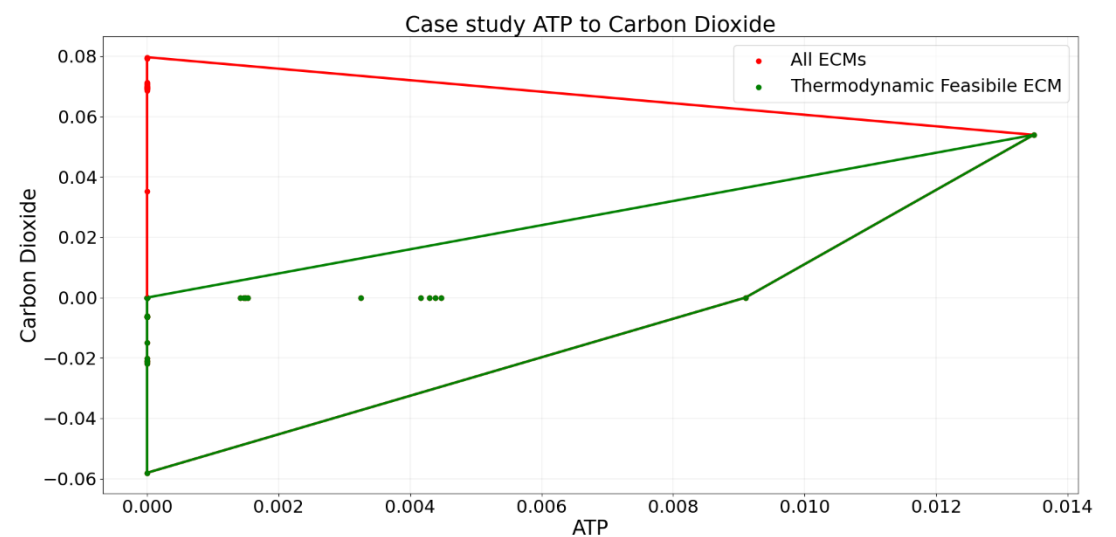

ECMs of the microbe Filamentous Anoxygenic Phototrophs

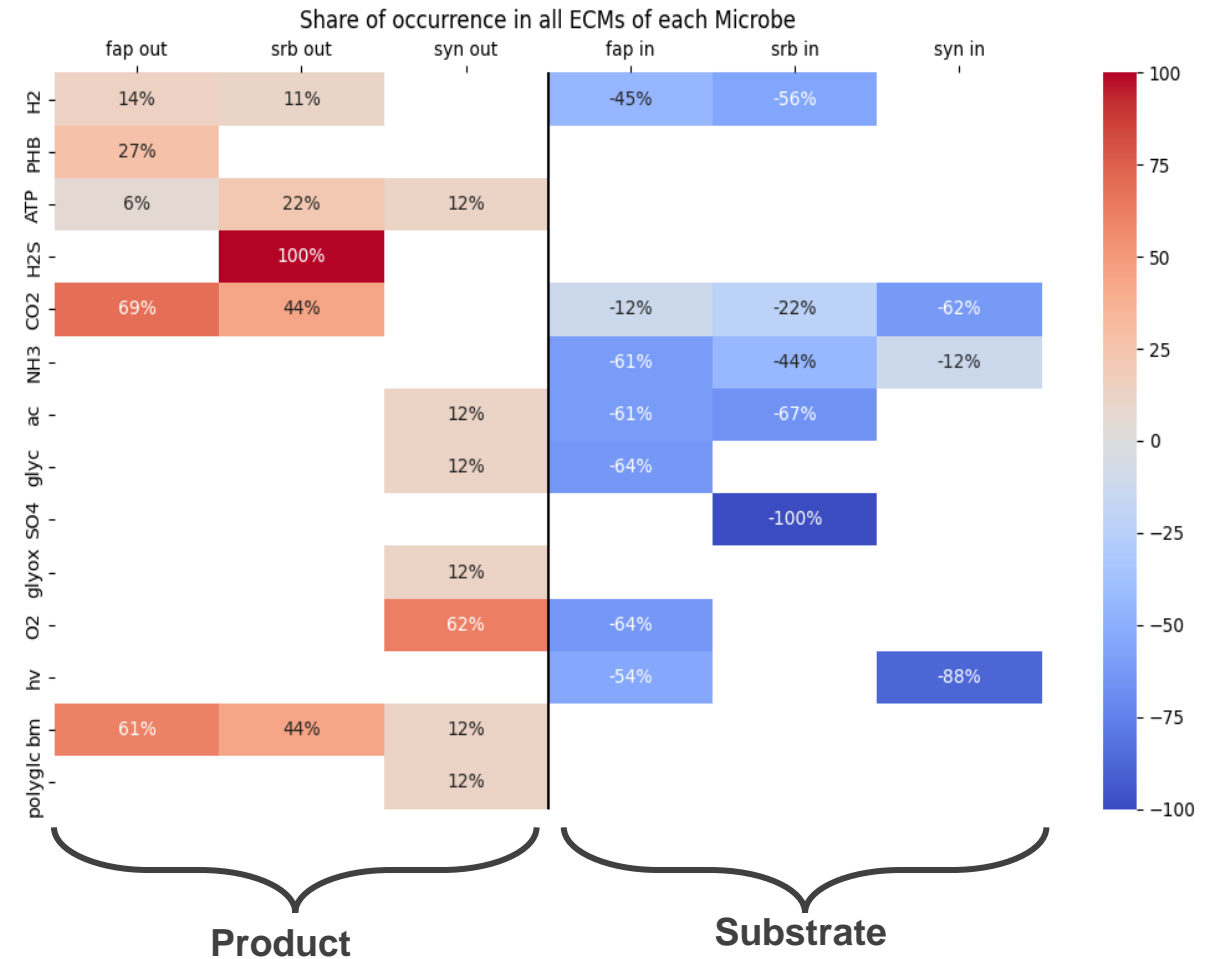

Solution Spaces Thermodynamic Feasibility

Case Study

- Genome Scale Metabolic Models of OMM19 strain were not available yet
- Data from three microbes of an community in a phototrophic microbial mats were used ^[1]
 - Filamentous anoxygenic phototrophs (FAP)
 - Synechococcus (SYN)
 - Sulfate reducing bacteria (SRB)
- Unicellular models were already build ^[2]
- ECMs were computed with the software ecmtool ^[3] and analyzed in this heatmap
- These models and all further models were build with the python library COBRApy

Compartmentalized Model

- All community members share a common internal space to exchange metabolites
- Every metabolite is keyed to its microbe

Pooled Model

- Every reaction and every metabolite is merged to one pooled organism
- Metabolites are unkeyed

Nested Model

?

Taffs et al. ^[1] applied these community model types on EFM

Community Model: Nested Model

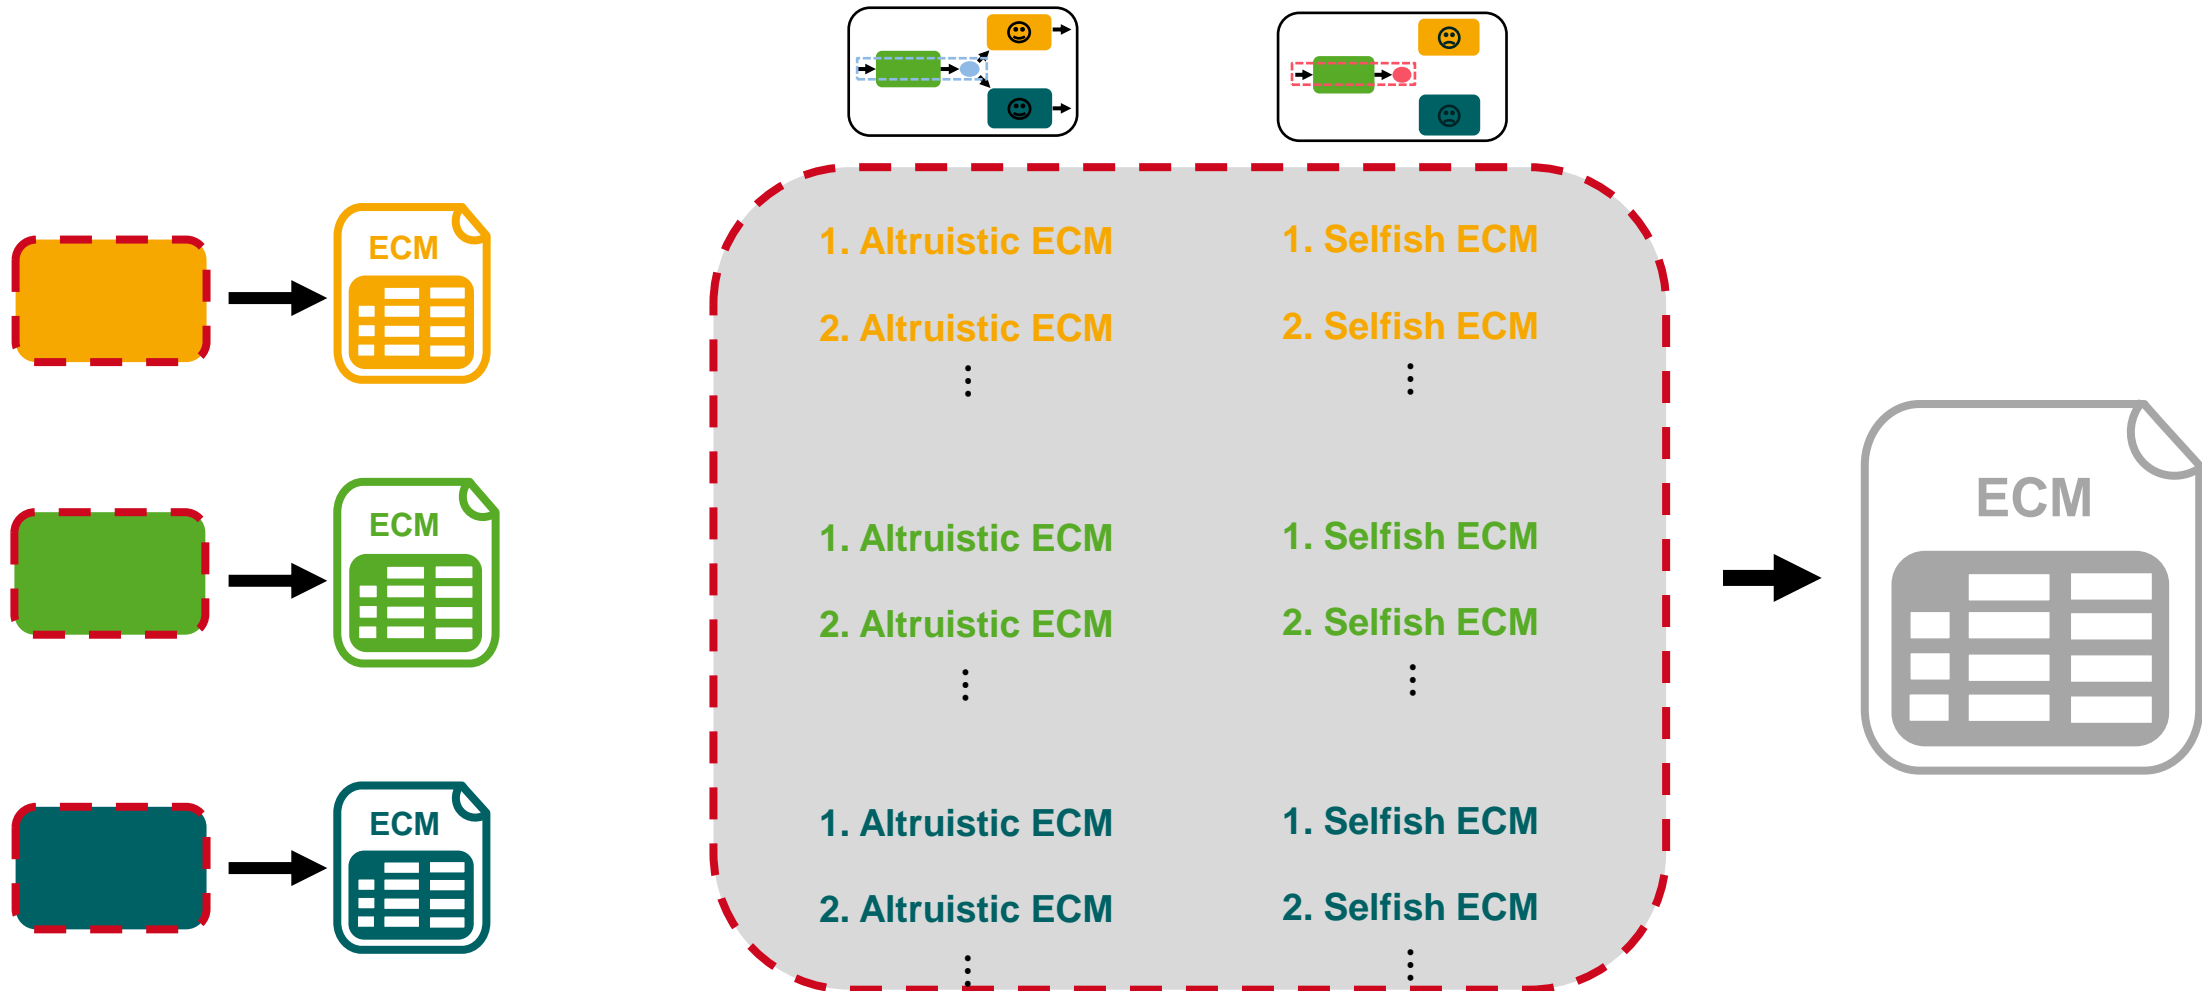

Altruistic ECM

max ● - efficiency

Selfish ECM

max ● - efficiency

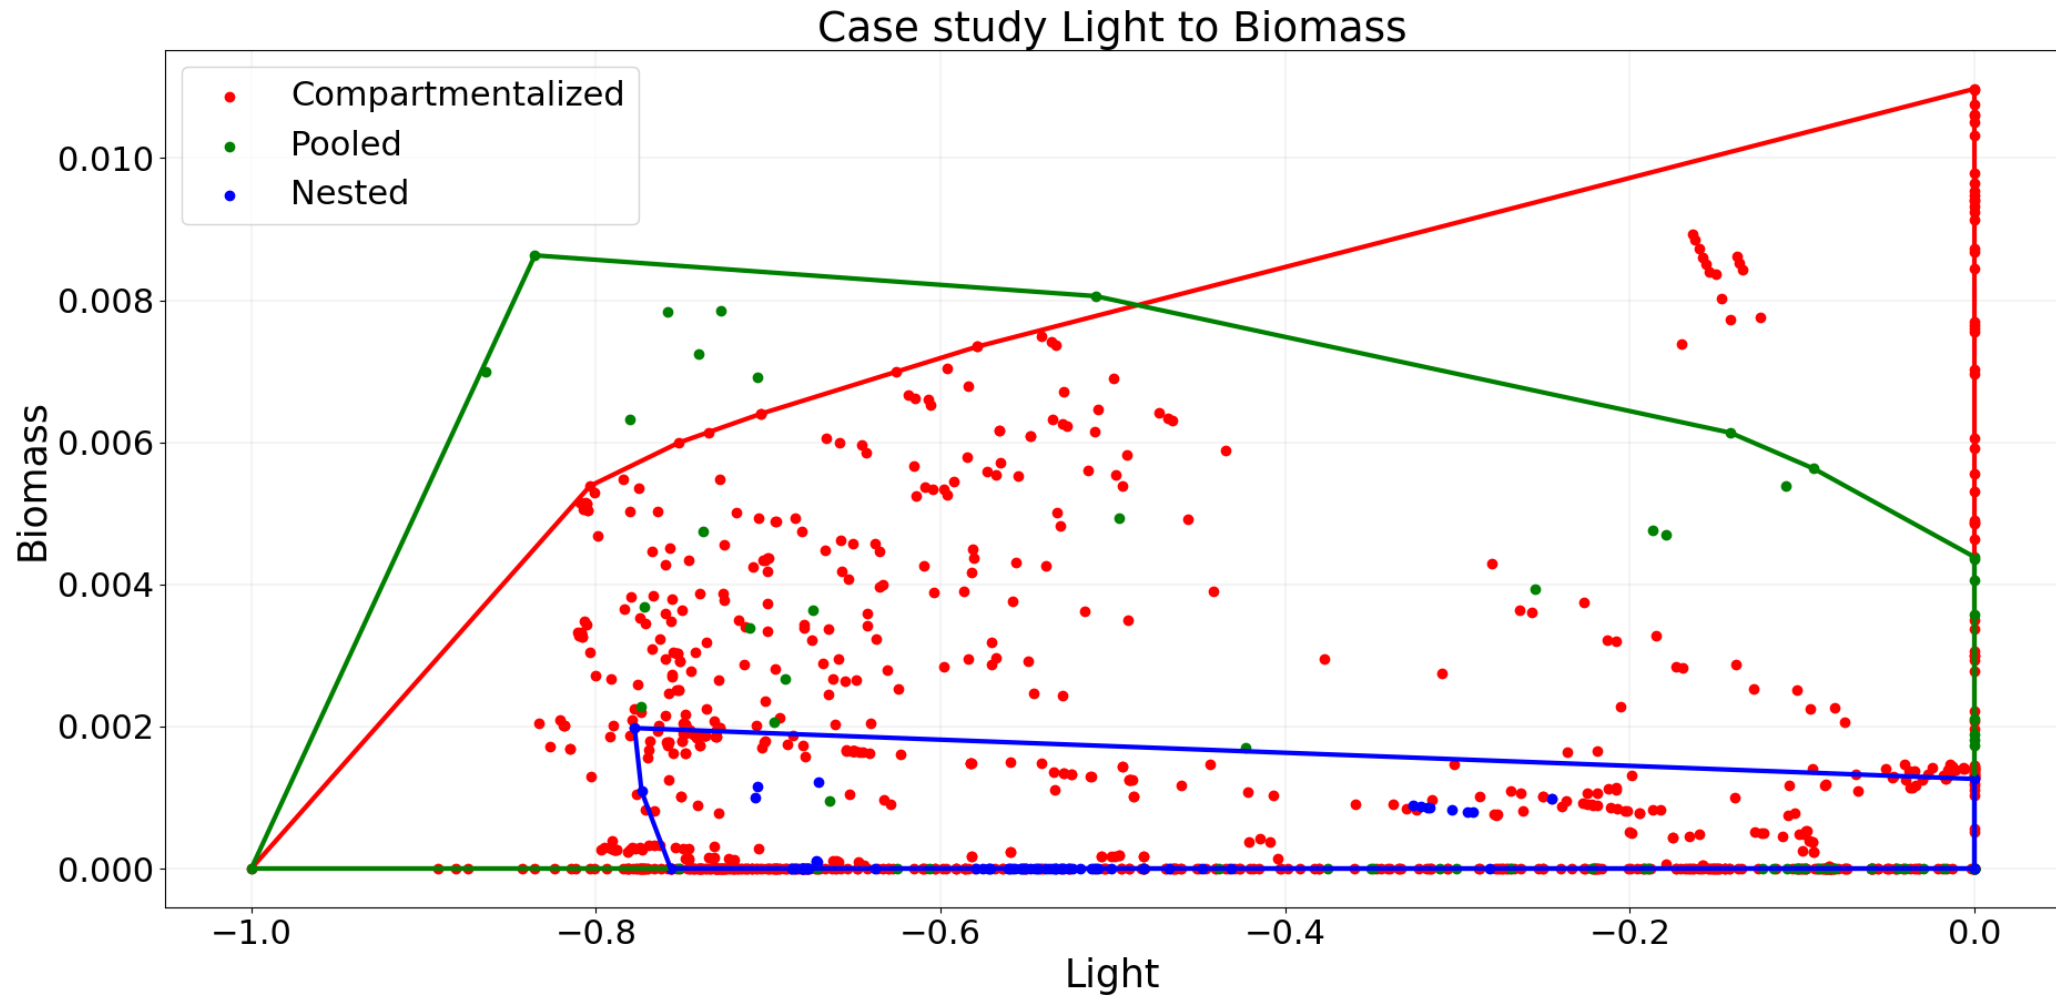

Community Model Comparison

Modeltype	+	-
Compartmentalized	<ul style="list-style-type: none">Detailed interaction network	<ul style="list-style-type: none">High computation cost
Pooled	<ul style="list-style-type: none">Low computation cost	<ul style="list-style-type: none">Hardly any interaction information
Nested	<ul style="list-style-type: none">Low computation costFocussed on relevant information	<ul style="list-style-type: none">Dependent on efficiency factorsDependent on number of chosen ECMs

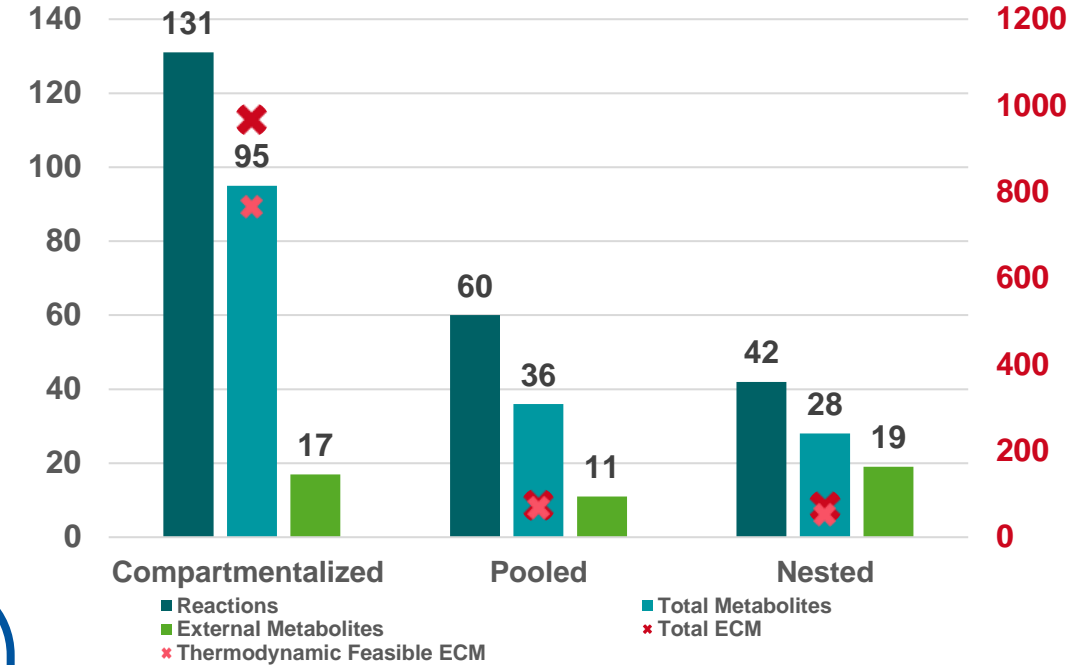

Conclusion and Outlook

Conclusion

- Analyzed ECMs
- Reduced solution space by thermodynamic feasibility
- Solved optimization with thermodynamic feasible ECM
- Built and compared 3 types of community models
- Data visualization

Outlook

- Validation of thermodynamic feasibility with concentration data
- Verify ECM models with BIOLOG data
- Application on Genome Scale Metabolic Models of the OMM19 strain

Thank you for your attention
